# Know 10 Native Plants

## About Community in Bloom

Community in Bloom (CIB) is a programme that was launched by the National Parks Board (NParks) in 2005. It aims to nurture a gardening culture among Singaporeans by encouraging and facilitating community gardening efforts. It is also an opportunity to build community bonds and strengthen social resilience in our City in Nature.

This brochure features

10 commonly cultivated native plants in Singapore. A native plant species is one that has occurred naturally in a place over a long time, and was not introduced from other places.

Plant species that have been introduced from other geographical regions are termed "exotic".

There are numerous varieties of native plants that can be grown in Singapore. We hope that this brochure will encourage you to try growing these plants in your own garden or in a community garden, and contribute to Singapore's natural heritage and environment.

## Why Grow Native Plants?

Native plants bring a host of benefits to any garden, including:

- Serving as a sustainable beginner planting palette as native plants require less fertilisers and pesticides, and are generally low maintenance
- Being excellent perimeter plants that add vibrancy and colour to your garden
  - Providing food and habitats for native wildlife, including beneficial pollinators such as bees and butterflies
- Letting you learn more about their traditional and cultural uses, such as a source of dye or plant fibre
- Contributing to Singapore's natural heritage and environment

## **Evaluating your environment**

Every garden is unique, so assessing your garden's conditions will help you in selecting the right plants. Choosing native plants that match your garden's environment is a good way to have a thriving garden, and will also teach you about Singapore's natural heritage. Keep an eye out in our coastal, forest and scrubland parks to see what thrives, and see if you can grow them in your garden too!

## **Environmental factors**

Sunlight is the most important factor that determines what plants you can grow. Gardens with long hours of full sunlight are ideal for many flowering native plants, while shady gardens with less than 4 hours of direct sunlight are more suitable for shade-loving native understory plants.

**Soil type** will also help define your plant selections. The soil in Singapore is naturally clayey, which is hard, dense, sticky and holds a lot of moisture. Most native plants thrive in this adverse soil type.

Drainage refers to how quickly water leaves your garden and this is closely linked to soil type.

Knowing how quickly your garden drains can help you choose plants that will require less maintenance.

Coastal native plants for example thrive on well-draining soil, while native plants from swamps or along streams do well in waterlogged areas.

## Soil types

Clayey soil is the most common soil type in Singapore. It is usually hard when dry and sticky when wet. Secondary forest edges, freshwater swamp areas and scrubland habitats in Singapore are typically composed of clayey soil. Plants from these environments are ideal for gardens that are newly built, or gardens that cannot have soil improvement done. Learn more about soil amendments in our NParksSG YouTube channel.

Sandy soil consists of small particles of gritty material like gravel, sand, stone and some organic matter. The coastal areas in Singapore have sandy soil and native coastal plants thrive in it.

## **Drainage**

Slow draining areas typically take more than 2 hours to drain after a storm and are usually indicative of clayey soil. Planting native plants that thrive in clayey soil will help the area with waterlogged conditions.

Fast draining areas do not form puddles even after heavy storms and are usually indicative of sandy soils. Native plants from coastal areas will thrive in such conditions and will not require as much watering as other types of plants despite the dry conditions.
