Abstract

A botanical survey of the Nature Reserves in Singapore conducted in 1992-93 resulted in the gathering of more than 2,600 vascular plant specimens. More than 600 species were represented, including two species not previously recorded from Singapore. The results of the survey are discussed in the paper.

Introduction

A botanical survey of the Singapore Nature Reserves was conducted in order to obtain a better understanding of their current flora. Emphasis was placed on the Central Catchment Area rather than Bukit Timah Nature Reserve as the former has been much less well investigated than the latter.

Methods

The survey used the technique of collecting fertile plant material to make voucher herbarium specimens which could be accurately identified and then used as a permanent record of the contemporary flora of the Nature Reserves. Teams of collectors visited all parts of the Central Catchment Area in the three month period of April-June 1992. More collections were made in the same months of the following year. Further sporadic collecting trips were made by the authors. When in the field, the teams endeavoured to collect specimens from all species of plants they found flowering, fruiting or sporulating. The teams used extension cutters which aid in the collection of material from heights of up to 5m. Clearly this meant that it was rarely possible to obtain fertile material from tall trees.

The specimens gathered were usually pressed in the late afternoon of the day of collection, or on the morning of the next day. Unpressed specimens were stored at 4 °C if they were kept overnight. The specimens were dried at 60 °C in a drying oven and then poisoned with 2.5 % (w/v) mercuric chloride in 95 % ethanol, redried and then mounted on acid-free paper. A few specimens were preserved in 70 % ethanol. The specimens were numbered in one Nature Reserves Survey (NRS) sequence (with the exception of a minority of collections recorded under personal series) and identified largely by matching to named specimens in the herbarium of the Singapore Botanic Gardens. Sets of specimens have been deposited in the herbarium of the Department of Botany, National University of Singapore (SINU) and the herbarium of the Singapore Botanic Gardens (SING).

A numbered grid square system was devised (Fig. 1) to localise the collections. Information on the NRS specimens has been entered into a computerized database.

Results

The NRS series reached 2613 over the collecting period, with a large number of duplicates gathered. Over 600 species (see Appendix 1) have been identified from the collections. Most of these species are small trees and shrubs, climbers, herbs and some aquatics reflecting our inability to make good collections from tall trees. Plants typical of secondary forest, which covers much of the Central Catchment Area, were found e.g. *Macaranga* spp., *Trema* spp., *Adinandra dumosa* and *Rhodunnia cinerea*, and a fair number of introduced and escaped plants e.g. *Hydrocera triflora*, *Ochna kirkii*, *Canna indica*, *Dioscorea sansibarensis*, *Wikstroemia ridleyi*, *Heliconia psittacorum* and *Cardiospermum halicacabum*. However, many native species more clearly associated with primary forest were also collected. These included trees and shrubs such as *Dracaena* spp., *Campnosperma squamatum*, *Canarium patentinervium*, *Lindera lucida*, *Litsea* spp., *Sterculia* spp., *Horsfieldia polyspherula*, *Gymnacranthera forbesii*, *Matthaea sancta*, and a number of species in the Rubiaceae and Euphorbiaceae. Climbers e.g. *Uvaria cordata*, *Pyramidanthe prismatica*, *Salacia grandiflora*, *Gnetum* spp., *Dissochaeta* spp., *Stephania capitata*, a number of members of the Vitaceae and many rattan species; and herbs such as *Amischotolype gracilis*, *Aglaonema* spp., *Mapania* spp., *Globba leucantha*, *Hanguana malayana*, *Peliosanthes teta*, *Stachyphrynum griffithii*, *Labisia pumila* and *Ophiorrhiza singaporenensis* are all good indicators of primary forest status wherever they are found.

Discussion

Without doubt the area that provided the most interesting specimens was the primary swamp forest around the SAF Firing Range at Nee Soon. It was the only site where several of the orchid species, such as *Bulbophyllum macranthum*, *Plocoglottis javanica*, and *Nephelaphyllum pulchrum* were collected. Other interesting species probably restricted to this, the last patch of swamp forest in Singapore, include *Kopsia singapurensis* and *Luvunga crassifolia*. The forest around the range still maintains a primary nature and contains some very large trees, though an alarming number are dead possibly reflecting a change in the drainage regime. Only Bukit Timah Nature Reserve can boast a vegetation as botanically exciting. It certainly merits the highest conservation status.

Elsewhere in the Central Catchment Area there are other patches of forest that approach the primary lowland forest type, most notably around MacRitchie Reservoir. Though most of the rest of the Catchment Area is covered with secondary forest, or even so degraded as to be reduced to lallang or resam stands, interesting plants can still be found. These areas are also of value in that they may represent future areas of colonisation for species currently restricted to tiny, fragmented primary areas. An expansion of range that is much to be encouraged as it will help ensure the future survival of those species in Singapore.

A number of the species collected were of particular interest. *Bulbophyllum gusdorfii* and *lodes cirrhosa* are new records for Singapore (Turner, Tan & Chua, 1994). *Daphniphyllum lauvinum* was found to occur when it had been reported as probably extinct in Singapore (Keng, 1990).
